

Monitoring volcanoes of the world with IMS infrasound network: evaluation of the reliability of a new detection algorithm

Duccio Gheri

Department of Earth Science University of Florence

INTRODUCTION

The detection and notification of ongoing volcanic eruptions are crucial for supporting the Volcanic Ash Advisory Centres, particularly in areas where local monitoring systems are absent at active Volcanoes. Long-range infrasound monitoring might provide useful information.

METHODS/DATA

A global scale Early Warning (EW) system, based on Infrasound Parameter (IP), is applied to 16 IMS infrasound array to detect volcanic explosive eruptions, between 2010 and 2019, where multiple eruptions with different VEI occurred.

START

RESULTS

The notifications of the algorithm are compared to the bulletin reports of the Global Volcanism Program (GVP). The EW system demonstrates its ability to not only detect major events ($VEI \geq 3$), but also reliably identify small persistent eruptions.

CONCLUSION

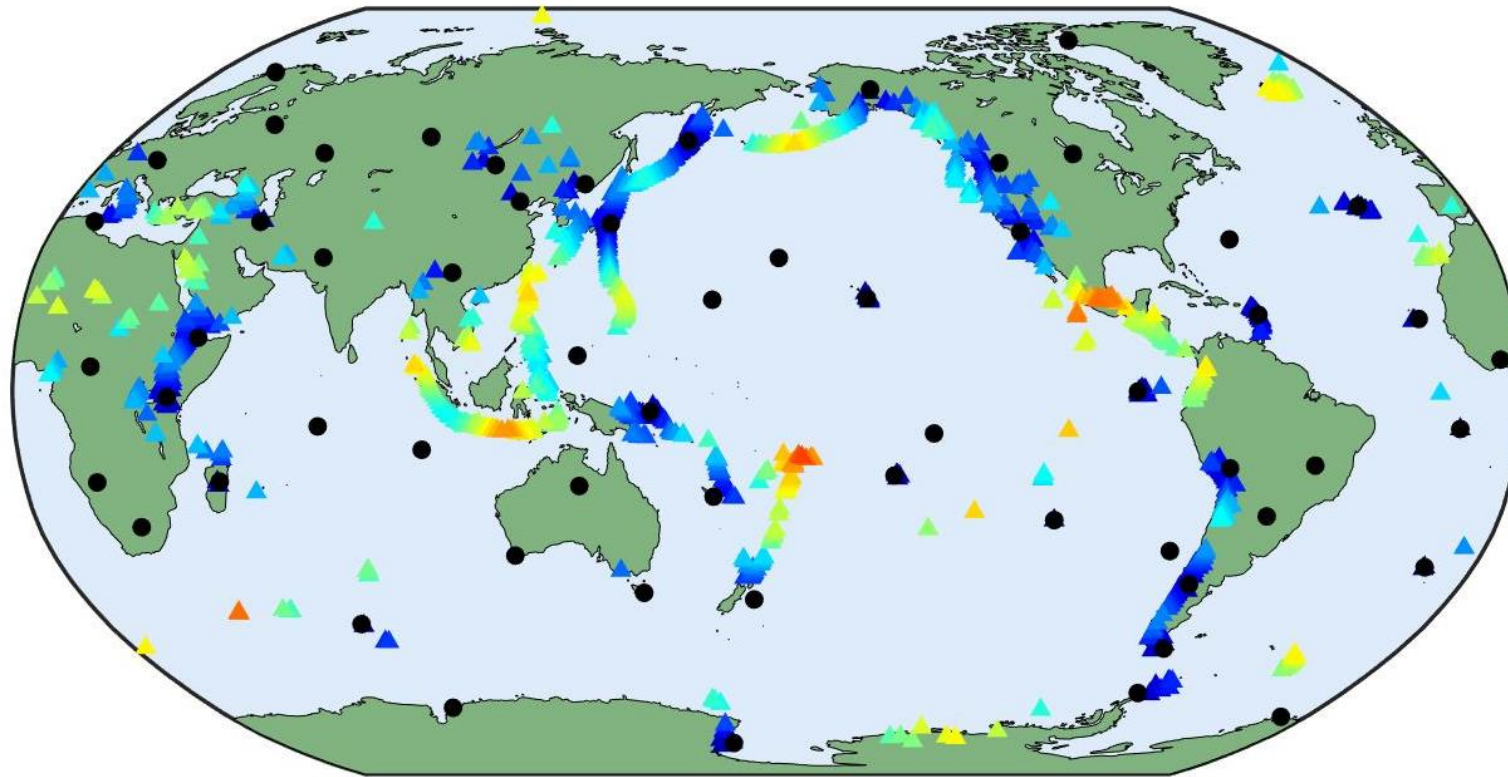

The algorithm's false alert rate has been assessed, and it is generally low for most volcanoes. Unresolved ambiguity remains due to short spacing among volcanoes with respect to the array and the unfavourable propagation conditions.

P5.2-478

~1500 active volcanoes on Earth
~68 erupt every year
5-6 eruptions per year with a **VEI ≥ 3**

Eruptions with a **VEI ≥ 3** can inject ash at elevation of **5-15 km** and thus potentially affect air traffic

Permanent and extensive monitoring is limited to few countries.
Many volcanoes worldwide are **poorly monitored**

Ulawun Eruption

Only ~2% of detections correspond to the eruption... and the others?

Long-range Volcano Infrasond Early Warning

$$IP = N_{det} \times Ps$$

N_{det} = Persistency of the signal
 Ps = infrasond pressure at the source

Results: Reliability on the notifications provided by the algorithm

$$R_{rel} = \frac{N_{ra}}{N_{TOT}} \times 100$$

N_{ra} is # of alerts that corresponds a volcanic eruption.
 N_{TOT} is # of alerts that the system delivers for the selected volcano.

- INTRODUCTION
- OBJECTIVES
- METHODS/DATA
- RESULTS
- CONCLUSION

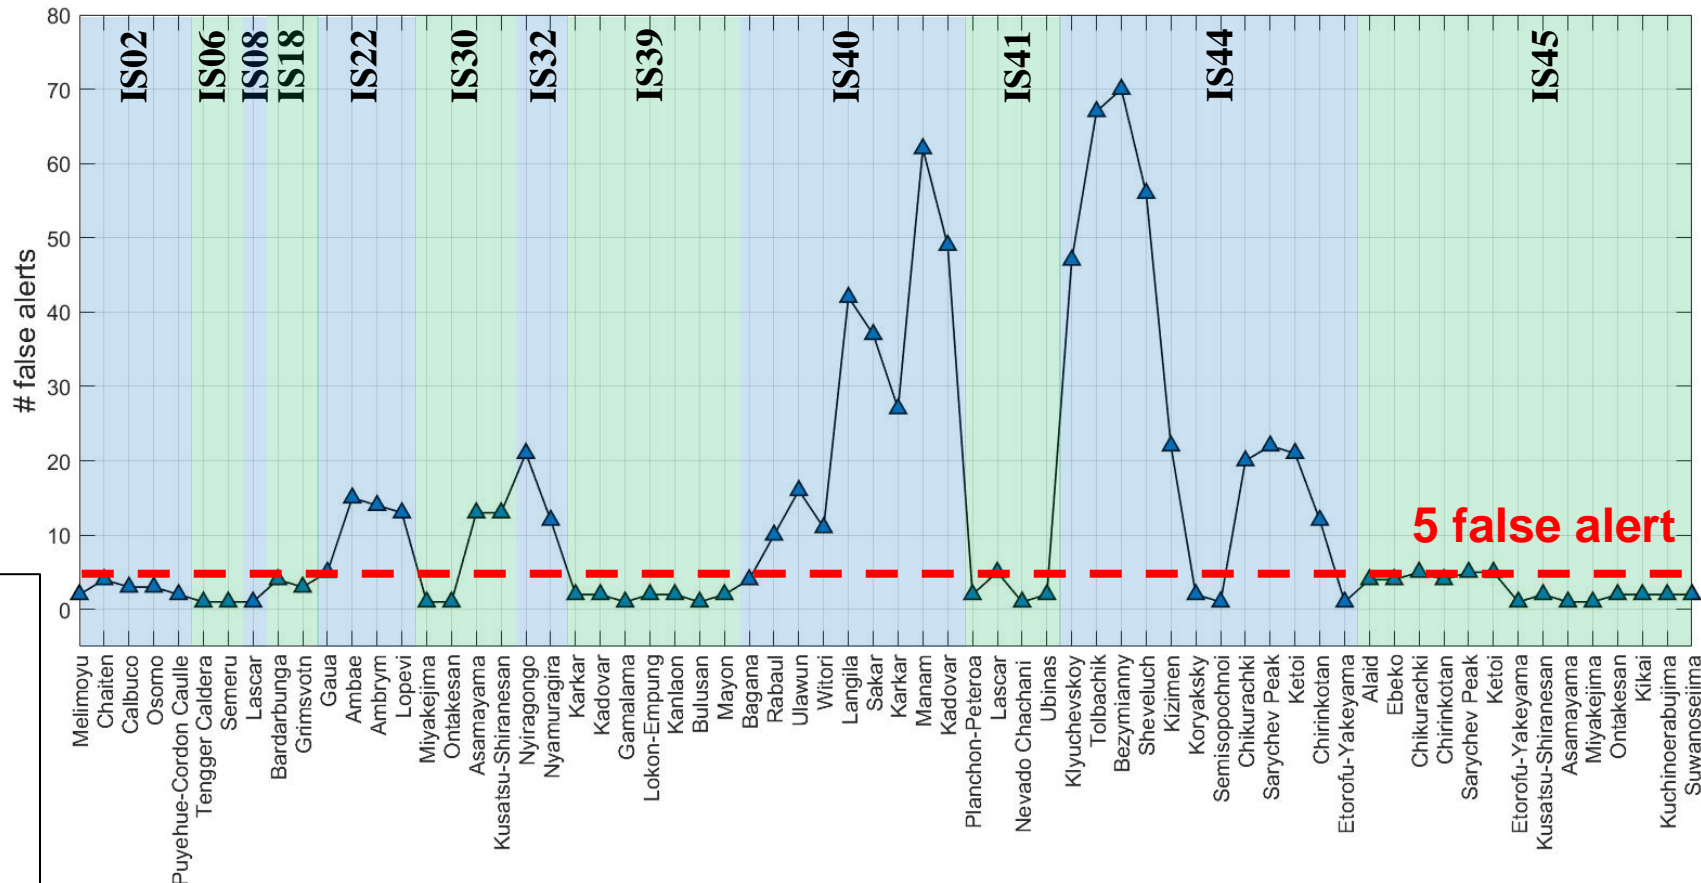

Please do not use this space, a QR code will be automatically overlaid

Conclusion: Some considerations on the EW algorithm and the first attempt to estimate the number of false alerts

Reliability Ratio R_{rel} (%)	Number of volcanoes
75-100	16
50-75	7
0-50	17
0	50
IND	61
TOT	151

For volcanoes with $R_{rel} \leq 50\%$, the algorithm provides a low rate of false alerts \rightarrow **0.5 false alerts per year for 42 volcanoes.**

Considering volcanoes with a $R_{rel} \geq 50\%$ and IND and low false alerts rate, **the number of potentially monitorable volcanoes is 126.**

Future steps:

- Expected Azimuth deviation correction.
- Validation with MIROVA.
