

Quality Control of Heterogeneous IMS Stations #336

Presenter: Kenneth A. Macpherson
Staff of Wilson Alaska Technical Center

This work was supported by the Nuclear Arms Control Technology
(NACT) Program at Defense Threat Reduction Agency (DTRA)

DISTRIBUTION STATEMENT: Cleared for Release

Introduction

Motivation: Detecting infrasonic or seismic events such as nuclear detonations is heavily dependent on data quality (DQ), and Station Operators are responsible for monitoring waveform data for completeness, transient noise, spikes, and changing or anomalous instrument response (*Marty, 2010*)

- The Wilson Alaska Technical Center (WATC) has long used an array of DQ tools to monitor state of health and completeness, but this project augments existing DQ procedures by adding a metric-based waveform data quality control (QC) scheme

Challenges: The diverse station-types monitored by WATC, which include infrasound and seismic arrays, broadband seismic, short-period seismic, and meteorological channels, are challenging for existing QC tools such as IRIS MUSTANG/ISPAQ (*Caset, et al., 2018*)

Approach: The new WATC QC system leverages existing tools, but has been built-out and customized to accommodate diverse channel types. We make heavy use of ObsPy to customize the system (*Beyreuther et al., 2010*)

Metric-based QC: Doctrine and Terminology

Metrics

a measurement (or algorithm to generate a measurement) that is indicative of some aspect of data quality

- facts
- observations
- raw data

dead_channel_lin = 1.8

Thresholds

a metric or combination of metrics combined with a cut-off value

- organize metrics
- identify and alert to potential data defects
- reduce analyst workload

num_gap/percent_availability > .12

dead_channel_lin < 2.0

Analysis

a human must investigate potential issues flagged by thresholds

- review issues
- inspect waveforms
- develop an interpretation
- provide actionable intelligence

Dead sensor at KDAK

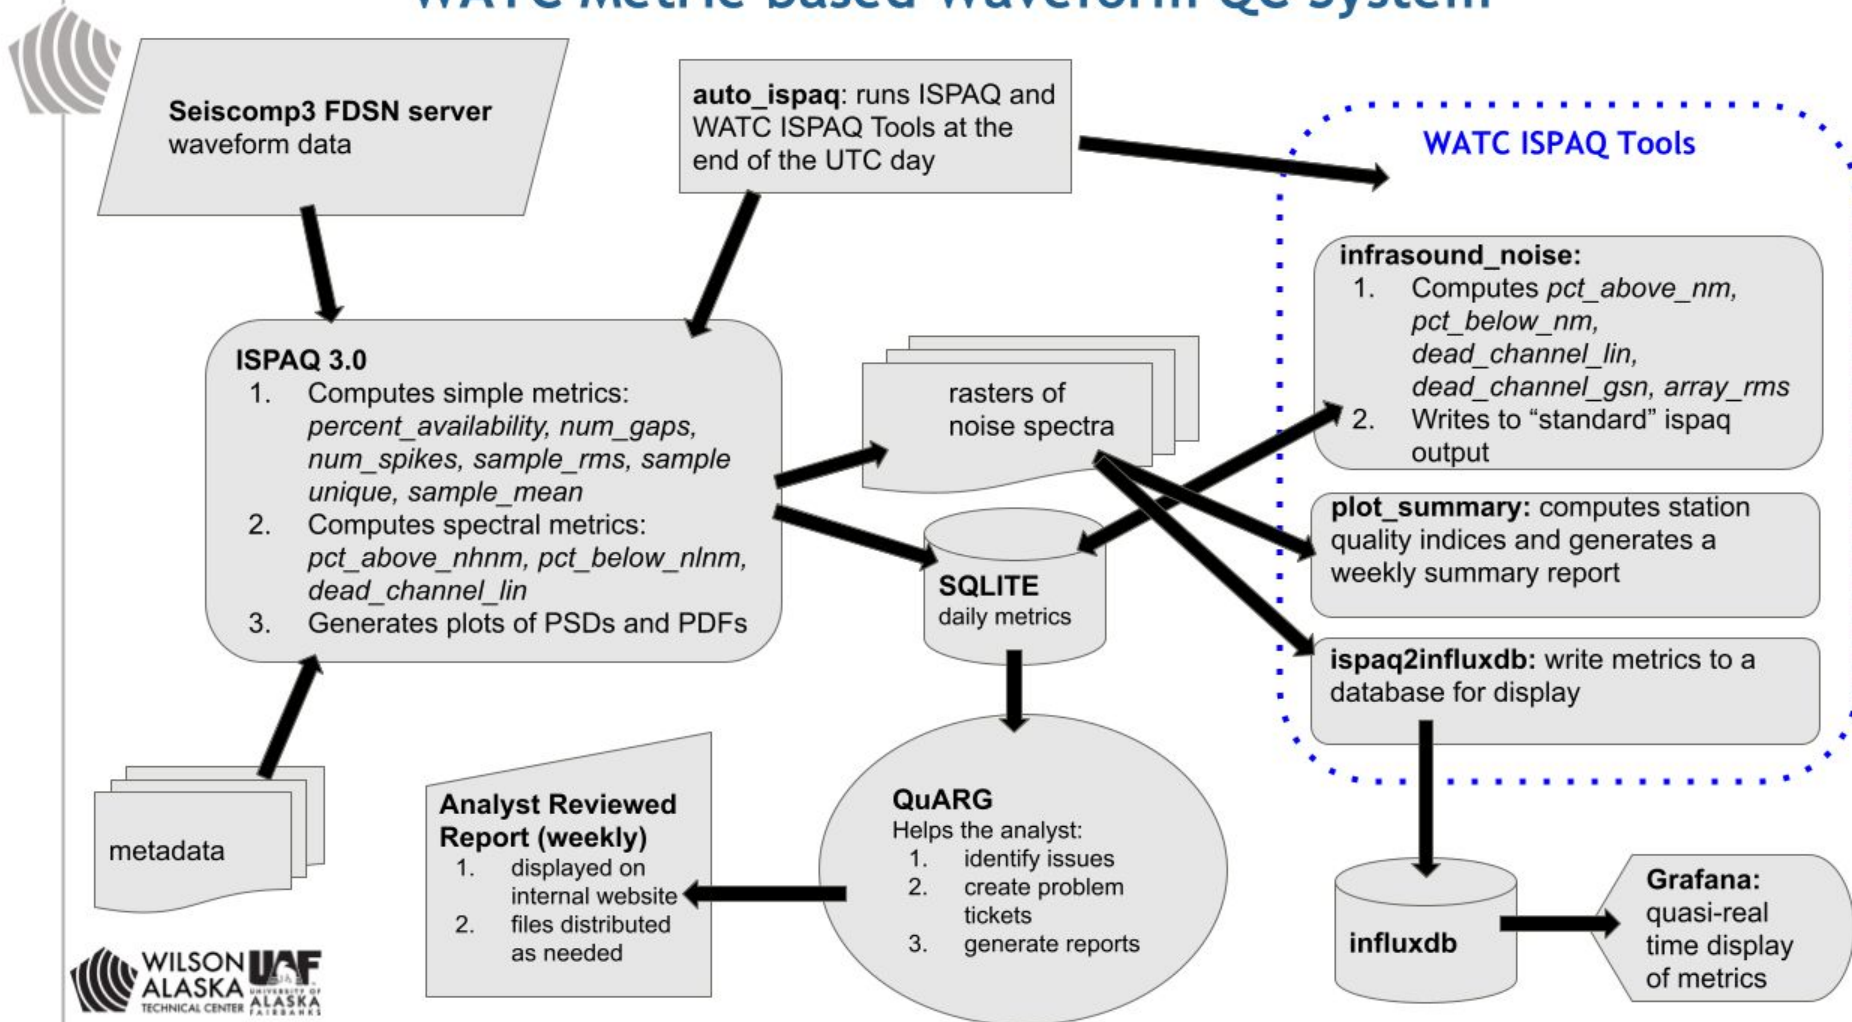

Core Software

- ISPAQ: IRIS System for Portable Assessment of Quality
 - Python/R code for station operators to generate MUSTANG metrics locally
 - 40 metrics available
 - ISPAQ 3.0 writes metrics to a SQLite database
- QuARG: Quality Assurance Report Generator
 - Uses thresholds to identify potential issues and alert the analyst
 - Generates QC report
 - Employs a ticketing system
- ObsPy: Python toolbox for seismology
 - Flexible through pull requests
 - Used to compute metrics for channels not currently handled by ISPAQ

WATC Metric-based Waveform QC System

Noise Spectra for Infrasound

- ISPAQ and ObsPy use the Mcnamara and Buland (2004) method of computing power spectral densities (PSD)
- This method differentiates seismic data to acceleration in the response removal stage, which is not required for infrasound
- We modified the ObsPy Signal library to correctly handle PSD/PDFs for infrasound
- Also added ambient acoustic noise models from Brown (2012)

```
# Create a psd object for infrasound chan  
tr = st[0]
```

```
ppsd = PPSD(tr.stats, metadata = inv,  
             special_handling = 'infrasound',  
             db_bins = (-100, 40, 1.))
```

```
ppsd.add(st)  
ppsd.plot(xaxis_frequency = True,  
          period_lim = (0.01, 10),  
          cmap=pqlx)
```

New feature!

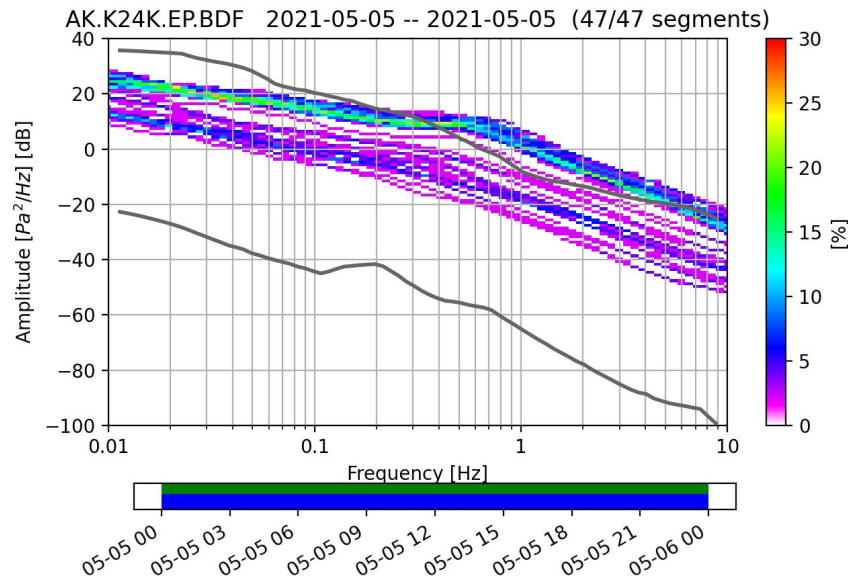

Noise Spectra for Infrasound

- We also added MUSTANG-like spectral metrics to the ObsPy PPSD object
 - `get_pct_above_nm()`: percentage of spectra above IDC high noise model
 - `get_pct_below_nm()`: percentage of spectra below IDC low noise model
 - `get_dead_channel_lin()`: residual from fitting a line to spectra
 - `get_dead_channel_gsn()`: spectra more than 5 dB below low model near the microbarom

```
In [8]: ppsd.get_pct_above_nm()  
Out[8]: 26.786688488816147  
In [9]: ppsd.get_pct_below_nm()  
Out[9]: 0.0  
In [10]: ppsd.get_dead_channel_lin()  
Out[10]: 3.6031948727904397  
In [11]: ppsd.get_dead_channel_gsn()  
Out[11]: 0
```

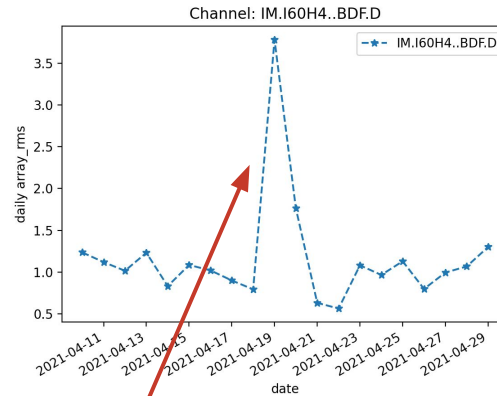

Custom Metrics

- The system is extensible and allows adding custom metrics
- **array_rms**: metric designed to detect transients on single element of an infrasound array
 - Grab 24 hours of data for all elements
 - Find the standard deviation of each element for the day
 - Find the mean of the standard deviation for all other elements
 - The metric is the ratio of the element standard deviation to the array average
 - If ratio is large, there is likely transient noise on a single element

For an n element array, the *array_rms* for the i th element is given by

$$array_rms_i = \frac{\sigma_i}{\bar{\sigma}_{[1,n]\setminus i}}$$

Where the numerator is the standard deviation of the i th element and the denominator is the mean standard deviation of the array excluding the i th element

Channel: AV.DLLH2.HDF.D
Date: 2021-04-19 to 2021-04-26
Status: Open

WATC has developed a metric-based **station quality index (Q_s)** to rate stations. A channel that is defect-free has a score of “1”, while a score of “0” would indicate an outage, digitizer noise, etc.

$$Q_s = \left(1 - \frac{1}{n} \sum_1^n dead_channel_gsn \right) \times \left(1 - \frac{\frac{1}{n} \sum_1^n pct_above_nm}{100} \right) \times \dots \times \left(1 - \frac{\frac{1}{n} \sum_1^n num_spikes}{max_num_spikes} \right) \times \left(1 - \frac{\frac{1}{n} \sum_1^n num_gaps}{max_num_gaps} \right) \times \left(\frac{\frac{1}{n} \sum_1^n percent_availability}{100} \right)$$

where n is the number of days

Conclusions

- We developed a **metric-based waveform QC scheme**, augmenting existing monitoring
- The system **accommodates diverse channel types** including seismic, infrasound, and environmental
- The system is **extensible** through the use of custom metrics
- The system **generates network intelligence** including completeness, transient detection, and spectral characteristics
- The system **communicates network intelligence** to engineers and data consumers in the form of weekly detailed and summary reports
